

Cell (Plasma) Membrane- Structure, Composition, Functions

- Membranes are lipid structures that separate the contents of the compartment they surround from its environment.
- Plasma membranes separate the cell from its environment while other membranes define the boundaries of organelles and provide a matrix upon which complex chemical reactions can occur.
- The plasma membrane, also known as the cell surface membrane or plasmalemma, defines the boundary of the cell.
- It is a phospholipid bilayer with embedded proteins that encloses every living cell.
- It regulates the movement of materials into and out of the cell and facilitates electrical signaling between them.
- It is said to be semi-permeable because it allows certain molecules but not others to enter into the cell.
- It serves some specific functions such as controlling the flow of nutrients and ions into and out of the cells, mediating the response of a cell to external stimuli (a process called signal transduction), and interacting with bordering cells.

CELL MEMBRANE

Structure and composition of plasma membrane

All biological membranes are constructed according to a standard pattern. They consist of a continuous bilayer of amphipathic lipids approximately 5 nm thick, into which proteins are embedded. In addition, some membranes also carry carbohydrates (mono- and oligosaccharides) on their exterior, which are bound to lipids and proteins. The proportions of lipids, proteins, and carbohydrates differ markedly depending on the type of cell and membrane.

- The plasma membrane consists of a **lipid bilayer** containing embedded and peripheral proteins. The major component of membranes is lipids.
