**Abstract:** The planning techniques and strategies for optimizing the urban wind and heat environment are important means for cities to adapt to climate change at the source. This study used Shenzhen, a sub-tropical megacity in southern China, as an example for evaluating the climate environment, heat island intensity, and urban form, and then for analyzing the relationships between them. The results revealed a high-quality climate area located southeast of Shenzhen that can provide a high wind speed and low temperature. Low-quality climate areas were located in the central and western regions and were less comfortable. The relationship between surface ventilation potential and urban form was analyzed using linear regression and the Pearson correlation coefficient, showing that there was a significant correlation between a surface urban heat island (SUHI) and building density (BD) as well as the sky view factor (SVF), and that there was also a correlation between the ventilation potential coefficient (VPC) and other factors, such as the surface's roughness length (RL) and building height (BH). The results showed that ventilation capacity deteriorated as BH and RL increased. An environmentally sensitive thermal area was identified from the surface urban heat island intensity, which was always in a strong heat island (SHI) or sub-strong heat island (SSH) year-round. It was recommended that seven level one corridors and nine level two corridors be formed. Additionally, thermal and wind environment optimization strategies and protective suggestions were proposed for the city's overall development.

## 1. Introduction

High-density urban buildings can cause significant changes in a local climate, resulting in lower wind speeds in urban blocks and exacerbating heat island effects and air pollution [1]. Hu et al. noted that the density (total building area) of an urban area is a decisive parameter affecting the urban heat island (UHI) intensity of that area; the higher the density is, the lower the SVF value is, which causes higher UHI intensity [2]. The research of Peng Wang et al. (2021) showed that urbanization significantly increases the frequency of hot extremes occurring in the summer, and that upward trends in human-perceived temperature (HPT) and actual near-surface air temperature (T) are more prominent in areas with higher urbanization levels and denser populations [3]. Liu (2021) explored the influence of the urban spatial morphology layout on urban heat islands and noted that spatial morphological parameters have become a more important driver of UHI changes than land surface parameters are [4].

In the past several decades, since Shenzhen was established as a special economic zone in 1980, its permanent population has increased from 330,000 to more than 13 mil-
