

Figure 16.13. Equilibrium diagram for the year 1910 in the third model.

new growth is within reach of the deer, so the *new growth available* is shown as 25,758 MT/yr. The *forage availability ratio* shows that this is 6.4 times larger than the *forage required*. The *fr forage needs met* will be 1.0 as long as the *forage availability ratio* is larger than 1.0. If the ratio should fall below 1, the *fr forage needs met* will fall as well. The *forage consumption* is the product of the *forage required* and the *fr forage needs met*. The *forage consumption* is subtracted from the *new growth* to find the *additions to standing biomass*.

Figure 16.13 shows no difference between the *forage required* and the *forage consumed*. This is to be expected when the deer herd is small. But if the deer population grows quite large, it is possible for the *forage required* to exceed the *new growth available*. When this happens, the *fr forage needs met* will fall below 1; the *forage consumption* will be limited; and the *net birth rate* will decline. If the *net birth rate* becomes negative, we will see a decline in the *deer population*. This new model appears to have the potential to generate the overshoot pattern of behavior.
