Microwave Oscillators and Amplifiers

Chairman

Jeffrey Frey

Some solid-state microwave devices — most noticeably, bipolar transistors and varactor diodes — have become increasingly common in microwave systems and, with the physics involved in their operation reasonably well understood, efforts are being made either to improve the basic parameters of these devices, or to design circuits for them with greater sophistication. Other devices — most notorious among these probably being the TRAPATT diode — are not so well understood, have not found widespread applications, and the required attempts at understanding how these devices can be optimally incorporated into microwave circuits, are now being made.

Authors of papers in this session will discuss both new circuit design techniques and technological modifications for the commonly-accepted bipolar transistors and varactor diodes; and with achieving a better understanding of how the operation of a TRAPATT diode depends on the circuit in which it is used, and how that dependence can be turned to advantage in circuit design.

Sophisticated circuit design methods, incorporating computer optimization and feedforward techniques, are being used to reduce distortion levels in high-power transistor amplifiers. The transistors themselves are being improved, in important (although not fundamental) ways, by the use of plated heat sinks (a technique long used by IMPATT diode fabricators) and the incorporation of matching networks on the transistor carrier itself. A novel metal-insulator-semiconductor (MIS) varactor diode improves upon the more usual junction varactor, by exhibiting capacitance saturation at large forward bias levels; a varactor with such a capacitance-voltage characteristic has been used in a paramp with a gain that is uniquely independent of pump level.

Finally, understanding of the operation of TRAPATT diodes has been enhanced by analyses of the effects of the actual external circuit on the behavior of the diodes. This work extends the usual approach to TRAPATT analysis, which starts with idealized impressed waveforms, in attempting to answer the questions of whether N⁺P or P⁺N diodes should be superior, and why; how circuits can be designed to minimize startup transients; and the effects of circuit loss, package parasitics, and diffusion currents, on performance.
