

Full Paper: A series of new regioregular poly(arylene ethynylene)s were prepared by Pd-catalyzed condensation of 3-hexyl multisubstituted oligothiophene derivatives with either benzene or anthracene compounds. The NMR characterization of the starting materials and model compounds lead to a thorough investigation of the corresponding macromolecules. Both small and large molecules were characterized by optical methods. The former, particularly when containing anthracene moieties, display noticeable photoluminescence quantum yields. In the polymers, the photoluminescence quantum yield is lower than that of the starting materials when anthracene is present, while the polymers containing benzene show higher quantum yields.

Introduction

Polymers consisting of regular sequences of arylene blocks with hetero residues have raised interest as electroluminescent layers in large-area light-emitting diodes (LED). Processable soluble conjugated polymers, such as poly[2,5-dialkoxy(phenylene vinylene)]s,^[1] poly[dibutylterthiophene(phenylene vinylene)]s,^[2] poly[dihexylterthiophene(phenylene azomethyne)]s,^[3] and poly[2,5-dialkoxy(*p*-phenylene ethynylene)]s,^[4] have recently been presented as emissive materials in the visible region for the preparation of LEDs.

The optical properties depend both on the nature of the arylene moiety – the best photoluminescence results are obtained using phenylene residues – and on the length of the arylene block between hetero-connections (—C≡C—, —C=N—, —C=C—). These factors together with the use of proper substituents allow the tuning of different colors in LED devices.

On the other hand, poly(thiophene ethynylene)-type polymers, having structures similar to those of poly(thiophene vinylene)s, have not been extensively studied. Very few works regarding the synthesis of polymers con-

stituted of alternating thiophene and acetylene moieties appeared.^[5] Sequences of 3-hexylthiophene acetylene and phenylene acetylene groups have been reported earlier by different authors.^[6] These polymers exhibited blue-light emission, the intensity of which being a function of the tactic character of the polymers due to a possible connection of the monomers either “head-to-head” or “head-to-tail”. In fact, Li and Pang observed different values of the photoluminescence quantum yield (PL QY), both in solution and in thin films for both poly(3-hexylthiophene ethynylene)^[7] and poly[(*p*-phenylene ethynylene)-*alt*-(3-hexylthiophene ethynylene)]^[8–11] although to a smaller extent as compared to poly(3-alkylthiophene)s.^[12]

Here, we report both on the synthesis of some dibromides and acetylene compounds of dihexylterthiophene and tetrahexylsexithiophene and on their Heck coupling in order to synthesize regularly alternating sequences of acetylene, phenylacetylene, anthracene units and hexyl-substituted oligothiophenes with three and six thiophene rings. We investigated the effect of the insertion of an anthracene moiety into thiophene-based polymers because of its luminescence properties.
