

Population Evolution

- The modern synthesis of evolutionary theory grew out of the cohesion of Darwin's, Wallace's, and Mendel's thoughts on evolution and heredity, along with the more modern study of population genetics
 - describes the evolution of populations and species, from small-scale changes among individuals to large-scale changes over paleontological time periods
 - To understand how organisms evolve, scientists can track populations' allele frequencies over time; if they differ from generation to generation, scientists can conclude that the population is not in Hardy-Weinberg equilibrium, and is thus evolving

Population Genetics

- Both genetic and environmental factors can cause phenotypic variation in a population
- Different alleles can confer different phenotypes, and different environments can also cause individuals to look or act differently; Only those differences encoded in an individual's genes, however, can pass to its offspring and, thus, be a target of natural selection.
- Natural selection works by selecting for alleles that confer beneficial traits or behaviors, while selecting against those for deleterious qualities.
- Genetic drift stems from the chance occurrence that some individuals in the gene line have more offspring than others.
- Mutations to an individual's DNA may introduce new variation into a population; Allele frequencies can also alter when individuals do not randomly mate with others in the group

Adaptive Evolution

- Because natural selection acts to increase the frequency of beneficial alleles and traits while decreasing the frequency of deleterious qualities, it is adaptive evolution.
- If the fit phenotypes are those that are similar, natural selection will result in stabilizing selection, and an overall decrease in the population's variation.
- Directional selection works to shift a population's variance toward a new, fit phenotype, as environmental conditions change; In contrast, diversifying selection results in increased genetic variance by selecting for two or more distinct phenotypes.
- frequency-dependent selection - individuals with either common (positive frequency-dependent selection) or rare (negative frequency-dependent selection) are selected.
- sexual selection results from one sex having more variance in the reproductive success than the other → males and females experience different selective pressures → evolution of phenotypic differences, or sexual dimorphisms, between the two.
