

Neural and Neurobehavioral Dysfunction in Children with Obstructive Sleep Apnea

Dean W. Beebe

Research has confirmed what many parents have long suspected: inadequate sleep in children is associated with daytime behavioral problems and poor academic functioning [1–3]. A fact less well-recognized by clinicians and the general public is that sleep-related breathing disorders, which occur in two to ten percent of children depending on how they are defined, can have a significant impact even among children who have normal sleep duration [4]. Snoring is a hallmark symptom of sleep-disordered breathing, and enlarged tonsils are often a contributing factor to the breathing disturbance. We still do not fully understand the mechanism that links snoring or enlarged tonsils with behavioral problems and poor grades.

One of the more severe nocturnal breathing disorders, obstructive sleep apnea (OSA), involves partial or complete breathing blockage recurrently during sleep, resulting in intermittent drops in blood oxygen levels and probable sleep disruption. Although brain processes are presumed to mediate the link between these medical factors and daytime behavioral and scholastic problems, our understanding of these processes remains fairly theoretical and speculative. The frontal and hippocampal regions of the brain, which are implicated in the regulation of behavior and memory, respectively, appear to be most vulnerable to OSA [4], but the evidence is indirect.

In a new study published in *PLoS Medicine*, Ann Halbower and colleagues [5] used proton magnetic resonance spectroscopy (MRS), a non-invasive neuroimaging technique that can detect chemical metabolites linked to neural dysfunction, to shed more direct light on the neural functioning of children with OSA.

The Study Findings

Halbower and colleagues compared two groups of children aged six to 16 years. The first group was comprised of 19 children who were referred by clinicians to a sleep medicine program and found to have moderate to severe untreated OSA. The control group was comprised of 12 non-snoring children who were recruited from community advertisements and who were of similar age, ethnicity, sex, and household income to the group with OSA. All participants underwent standardized evaluations of their thinking skills, and most also underwent MRS.

Inadequate sleep in children is associated with daytime behavioral problems and poor academic functioning.

Compared with the controls, children with OSA scored significantly lower on tests of overall intelligence and some aspects of higher-level thinking called “executive functions,” but the groups did not differ on tests of sustained attention, motor skills, or visuospatial skills. Tests of memory did not yield significant differences between the groups, but the effect sizes were large enough for the authors to suggest that significant effects might have been found in a larger sample. MRS indicated that those with OSA had abnormal metabolites in the left hippocampus and right frontal cortex.

Implications for Brain Development and Clinical Practice

These parallel findings of deficits on measures of behavioral and brain functioning in children with OSA are sobering, and lend support to concerns that OSA, if left untreated, can have substantial long-term adverse effects [4,6,7]. The developing brain does not simply unfold in a predetermined genetic process. Rather, it builds upon

itself at each stage, with development dictated by the interaction of genes with the immediate cellular environment [8]. That environment is determined by the child’s life experiences (e.g., reactions to OSA-related behavioral disturbances) and physiological functioning (e.g., OSA-related oxygen deprivation or sleep disruption). For this reason, untreated childhood OSA may have a particularly marked long-term impact.

If Halbower and colleagues’ findings hold in follow-up research, pediatricians and other health-care professionals will need to become much better at consistently screening for symptoms of OSA. Sleep is rarely addressed in most pediatric clinics [9,10], even though simple clinical screening tools have been developed and tested [10]. This lack of clinical attention runs contrary to current evidence from sleep medicine and developmental neuroscience, which suggests that early disease detection and treatment should be a high priority.
